ABSTRACT

A few high-quality prairies still exist in the sand deposits of the Green River Lowlands. The most extensive remnants are in the Green River State Wildlife Area, Lee County, Illinois. Three upland prairie communities were surveyed; a dry sand prairie dominated by *Schizachyrium scoparium*, *Ambrosia psilostachya*, and *Amorpha canescens*; a dry-mesic sand prairie dominated by *Sorghastrum nutans*, *Schizachyrium scoparium*, *Antennaria plantaginifolia*, and *Liatris aspera*; and a mesic sand prairie where *Sorghastrum nutans* and *Andropogon gerardii* were the dominant grasses, and *Parthenium integrifolium*, *Fragaria virginiana*, *Liatris pycnostachya*, and *Euthamia gymnospermoides* the common forbs. The lowlands, which included approximately 325 ha, were dominated by the exotic *Phalaris arundinacea*, but high-quality wet sand prairie, sedge meadow, and marsh communities existed. The wet sand prairies were dominated by *Spartina pectinata*, *Helianthus grosseserratus*, and *Solidago canadensis*; the sedge meadows were dominated by *Carex haydenii*, *Calamagrostis canadensis*, and *Persicaria coccinea*; the marsh communities were divided into distinct vegetation zones. These vegetation zones were surveyed in 2002 and subjected to an extensive uncontrolled fire in 2005. Surveys completed in 2006 and 2007 were used to determine successional changes resulting from the fire. These studies suggested that most communities were returning to the species composition found before the 2005 fire.

INTRODUCTION

Sand deposits are relatively common in the northern half of Illinois, accounting for about 5% of the land area of the state. Most occur on glacial outwash plains resulting from erosion events associated with Wisconsin glaciation (Wildman and Frye 1970, King 1981). One extensive sand deposit is the Green River Lowlands in parts of Bureau, Henry, Lee, and Whiteside counties in northwestern Illinois. Located just to the west of the terminal moraine of Wisconsin glaciation, extensive amounts of sand and gravel were deposited in these areas during intermittent warm periods of the Wisconsin Episode (Killey 1998). These sands were reworked by wind, creating numerous small sand dune fields (Willman and Frye 1970).

These sand deposits are scattered throughout the Green River Lowland Section of the Grand Prairie Natural Division (Schwegman 1973). This section, which includes the broad valley of the Green River and lower Rock River, was formed about 10,000 years ago during the retreat of Wisconsin glaciation (Willman and Frye 1970). During early European settlement this section had extensive marshes and wet prairies associated with the Great Inlet Swamp that covered part of Lee County (Lyman 1901, McClain 1992, McClain and Ebinger 2000).

Sand deposits containing numerous small dunes were common. Forests and savanna communities grew on the dry sandy ridges, while floodplain forests occurred along the rivers. In recent history, grazing, drainage, and cultivation have disturbed nearly all of this section, while fire suppression has resulted in the formation of many poor-quality sand forests containing numerous early successional and non-native (exotic) species.

Gleason (1910) referred to the vegetation of the Green River Lowlands in his extensive study of the Illinois sand deposits. Until recently that study was the only reference available of the flora of this region. Phillippe et al. (2000, 2003) studied some of the sand prairie communities at the Green River State Wildlife Area (GRSWA), Handel et al. (2003) examined the sand prairie remnants and sedge meadows of the Richardson Wildlife Foundation, a private hunting club, and McClain et al. (2003) examined the vegetation of a dune ridge at Foley Sand Prairie Nature Preserve. The purpose of the present study was to determine the composition and structure of the vegetation of the sand communities present in the GRSWA. Also, as the result of an extensive uncontrolled fire in the marsh community of the GRSWA in 2005, we examined the changes in the vegetation of this area in 2006 and 2007.

STUDY AREA

The GRSWA, located in the southwestern part of Lee County, about 23 km south of Dixon, Illinois (S7, S8, S17, S18, T19N R9E and S12, S13 T19N R8E), is the most extensive area in public ownership in the Green River Lowlands (Ebinger et al. 2008) (Fig. 1). The initial purchase of land started in 1938 under the Federal Aid in Wildlife Restoration Act to provide habitat for waterfowl and dwindling populations of the Greater Prairie Chicken (*Tympanuchus cupido*). Subsequent land purchases increased the size of the GRSWA to 1,025 ha (2,533 acres). The area was under

intense grazing pressure prior to 1938, and was subject to much brush encroachment resulting from fire suppression until 1987. Much of the grasslands of the GRSWA were mowed annually from June through September until 1998 (Todd Bittner, personal observations). During the natural areas inventory in the mid-1970s no high-quality natural areas were reported for the GRSWA (White 1978).

Since 1993 an active management program at the GRSWA has been implemented, including burning, brush removal, restoration plantings, and exotic species control. In addition to prescribed fire used to manage the prairie communities, most of the forested areas,

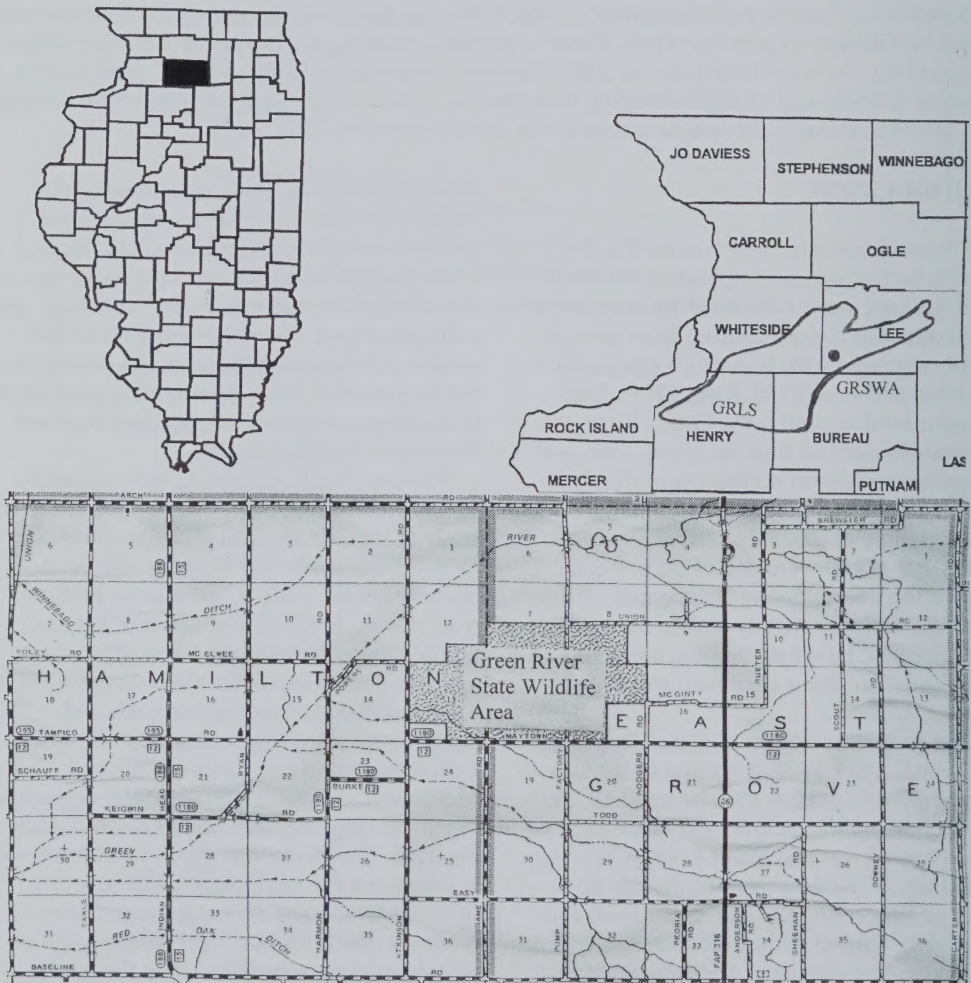

Figure 1. Location of the Green River State Wildlife Area (GRSWA) in the Green River Lowland Section (GRLS) of the Grand Prairie Natural Division, about 24 km south of Dixon, Lee County, Illinois .

including the woody understory, were removed in the fall and winter of 2001. Beginning in 1987, many of the the dry, dry-mesic, and mesic sand prairies were intentionally burned every one to three years. Presently this multiple-use area is managed for the protection and enhancement of wildlife and natural heritage resources.

The soils of the uplands at the GRSWA are Billett fine sandy loam, Chelsea fine sand, and Sparta loamy sand (Zwicker 1985). These soils, which occur on side slopes and ridges of dunes, are relatively low in organic matter, well drained, and have a surface layer of dark gray to yellow brown friable fine sand. The wetland soils are Adrian muck, Gilford fine sandy loam, Orio mucky sandy loam, and Orio sandy loam. Very high in organic material, these soils occur on level, poorly drained outwash plains and contain surface water for much of the winter and early spring.

On 18 October 2005 the extensive marsh located at the western portion of the GRSWA was burned in an attempt to decrease the growth of the exotic species *Phalaris arundinacea* (Lavergne and Molofsky 2006). Dry conditions at the time of the controlled burn resulted in extensive peat fires, some of which continued to burn for approximately 30 days. Water was pumped into some areas of the marsh from central pivot irrigation wells located on surrounding farms, and some fires were repeatedly disked and flooded.

The climate in northwestern Illinois is continental with warm summers and cold winters. Based on weather data from Dixon, located near the north-central edge of the Green River Lowlands, the mean annual precipitation is 94.7 cm, June having the highest rainfall (12.4 cm), and February the lowest (3.6 cm). Mean annual temperature is 8.5°C with the hottest month being July (average of 22.3°C), and the coldest January (average of -7.9°C). There are an average of 161 frost-free days (Midwestern Regional Climate Center 2008).

METHODS

Vascular Plant Species and Communities:

The natural areas studied were visited at various times throughout the growing seasons of 2000 through 2007. Voucher specimens of each plant species were collected, identified, and deposited in the herbarium of the Illinois Natural History

Survey, Champaign, Illinois (ILLS), and the Stover-Ebinger Herbarium of Eastern Illinois University, Charleston, Illinois (EIU). Criteria for designating non-native species followed Mohlenbrock (2002), Gleason and Cronquist (1991), and Taft et al. (1997). Nomenclature follows Mohlenbrock (2002). The plant communities encountered were designated and plotted using the classification system of White and Madany (1978). The locations of threatened and endangered plant species were recorded (Herkert and Ebinger 2002).

The Floristic Quality Index (FQI) was determined for each community type using the coefficient of conservatism (CC) assigned each species based on a species tolerance to disturbance and its fidelity to habitat integrity (Taft et al. 1997). The FQI, therefore, is a weighted index of species richness (N = number of species present on a site), and is the arithmetic product of the average coefficient of conservatism (C -Value = the average of all species CCs) multiplied by the square root of the species richness (\sqrt{N}) of an inventory site: $FQI = C\text{-Value} (\sqrt{N})$. For relatively small areas that are intensively studied, the FQI gives a rapid means of comparison and an indication of the floristic integrity of the site. Using the FQI along with other floristic measures, such as quadrat-based sampling methods, provide a way to make comparisons among sites. Prairies with an FQI of 35 or higher are considered high-quality natural areas (Taft et al. 1997). All species recorded for the plots as well as all other species observed in the community were used to determine the FQI of each site.

The Sorensen Index of Similarity (ISs) was used to determine the degree of vegetation similarity among the prairie areas surveyed throughout the Mississippi River sand deposits (Mueller-Dombois and Ellenberg 1974). In this index $[ISs = 2C/(A+B) \times 100]$, where A equals the number of species in the first community, B equals the number of species in the second community, while C equals the number of species common between the two communities.

Ground Layer Sampling: In mid-summer of 2003 through 2007 line transects were located randomly along cardinal compass directions within the sand prairies, sedge meadows, and marsh communities. Many of the sites were sampled two or three times during the study; the starting points of each transect were

marked with metal stakes and relocated using GPS coordinates during each survey. The dry, dry-mesic, mesic, and wet sand prairies were surveyed once (2006), whereas the marsh communities were surveyed in 2002, and again in 2006 and 2007 after a very hot uncontrolled fire burned the marsh in 2005. The sedge meadow located next to a wet sand prairie was surveyed in 2006, and the sedge meadow associated with the marsh in 2002, 2006, and 2007. Two transects were randomly located within each community; along each transect, 1m² plots were located at 1- or 5-m intervals (on larger sites the plots were more widely spaced) on alternating sides of the transects (n=50). A random numbers table was used to determine the number of meters (0 to 9) a plot was located from the transect line. Species cover was determined using the Daubenmire (1959) cover class system as modified by Bailey and Poulton (1968). Only ground layer species rooted within the plot frame were recorded. The modified Daubenmire cover scale is as follows: class 1 = 0 to 1%; class 2 = >1 to 5%; class 3 = >5 to 25%; class 4 = >25 to 50%; class 5 = >50 to 75%; class 6 = >75 to 95%; class 7 = >95 to

100%. Importance value (IV) was determined by summing relative cover and relative frequency. The location of the community study sites are shown in Figure 2 along with extent of the marsh at the GRSWA and the area burned in 2005.

Forest Sampling: In the summer of 2001 the overstory of the forests at the GRSWA were sampled using circular plots 0.3 ha in size, spaced at 25-m intervals along line transects (n=10). Within each plot all living individuals ≥10.0 cm dbh were identified and diameters recorded. From these data, living-stem density (stems/ha), basal area (m²/ha), relative density, relative dominance, importance value (IV), and average diameter (cm) were calculated for each species. Determination of the IV followed the procedure used by McIntosh (1957), and is the sum of the relative density and relative dominance (basal area). Woody understory composition and density (stems/ha) were determined using nested circular plots 0.0001, 0.001, and 0.01 ha in size, located at 15-m intervals along randomly located east-west transects within each study area. Four additional 0.0001-ha

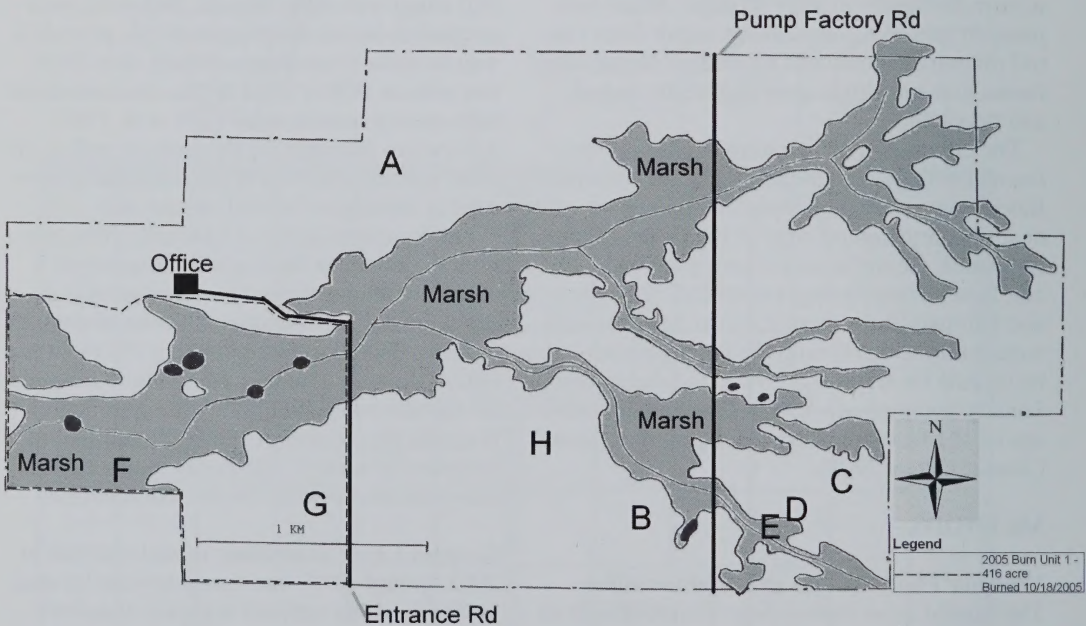

Figure 2. The location of the community studied at the GRSWA along with extent of the marsh and the area burned in 2005. A—dry sand prairie, B—dry-mesic sand prairie, C—mesic sand prairie, D—wet sand prairie, E—sedge meadow (east), F—sedge meadow (west), G—successional lowland, and H—successional upland.

circular plots were located 6 m from the center point of each plot along cardinal compass directions. In the 0.0001-ha plots, woody seedlings (≤ 50 cm tall) were counted; in the 0.001-ha circular plots small saplings (> 50 cm tall and < 2.5 cm dbh) were recorded; and in the 0.01-ha circular plots large saplings (2.5 – < 10.0 cm dbh) were tallied.

During the late fall and winter of 2001, these forested areas, including their woody understory, were removed to reestablish prairie vegetation. The bare sand and woody waste were left on the sites and no prairie seed was planted. The resulting lowland and upland successional communities were examined in 2002, 2003, and 2006. Within each community four transects were randomly located. Along each transect, 1-m² plots were located at 1-m intervals alternately along transects ($n=100$). A random numbers table was used to determine the number of meters (0 to 9) a plot was located from the transect line. Species cover was determined using the Daubenmire (1959) cover class system as modified by Bailey and Poulton (1968). Importance values were determined by summing relative cover and relative frequency.

Aerial photographs from 1939, 1951, 1970, and 1988 were digitized to determine woody encroachment (trees and large shrubs) at the GRSWA. These aerial photographs were borrowed from the University of Illinois Map Library and scanned with a Microtek ScanMaker. Twenty-one stratified random 5-ha sites, approximately 10.12% of the GRSWA, were interpreted and then digitized using ARC/INFO. The 1939, 1951, and 1970 photographic surveys were all flown in August whereas the 1988 aerial survey was flown in April.

RESULTS

Dry Sand Prairie: One high-quality dry sand prairie was encountered on the GRSWA (SW1/4 SW1/4 S7 T19N R9E; Fig. 2). This site, approximately 2 ha in size, was located on the ridge and upper slopes of a large stabilized sand dune composed of Chelsea fine sand. The dominant grasses, which did not exceed 1 m in height, were *Schizachyrium scoparium*, *Koeleria macrantha*, *Dichanthelium villosissimum*, and *Leptoloma cognatum*. *Ambrosia psilostachya* ranked second in importance, while other common forbs included *Chrysopsis camporum*, *Solidago nemoralis*, and *Coreopsis lanceolata* (Table 1). *Amorpha*

canescens, *Rosa carolina*, and *Rhus aromatica* were the only woody species encountered in the plots. Based on the Sorensen Index of Similarity the dry sand prairie was very similar to the dry mesic sand prairie, but had no species in common with the sedge meadows (Table 2). Within the dry sand prairie, 48 taxa were recorded in the plots, including 4 exotic species, *Achillea millefolium* being the most important. Average bare ground and litter was 29%, the vegetation being relatively sparse. A total of 94 species were observed in the dry sand prairie for an FQI of 36.16 and a mean CC of 3.73.

Dry-mesic Sand Prairie: On the east side of the GRSWA was a dry-mesic sand prairie on Chelsea fine sand. This sand prairie, covering 3 ha, occupied the dune ridge and upper dune slopes (NE1/4 SW1/4 S17 T19N R9E; Fig. 2). The dominant grasses, which were between 0.9 and 1.3 m tall, included *Sorghastrum nutans* and *Schizachyrium scoparium*. Other relatively common grasses were shorter and included *Dichanthelium villosissimum*, *D. oligosanthos*, *D. perlongum*, and *Leptoloma cognatum* (Table 1). Important forbs included *Antennaria plantaginifolia*, *Liatris aspera*, *Euthamia gymnospermoides*, and *Euphorbia corollata*. *Antennaria plantaginifolia* commonly covered small areas in a near monoculture. Based on the Sorensen Index of Similarity, the dry-mesic and mesic prairies were similar but had only a few species in common with the wet prairies and sedge meadows (Table 2). Within the dry-mesic sand prairie, 37 species were found in the plots, including three exotic species, *Rumex acetosella*, *Poa pratensis*, and *Achillea millefolium*. Vegetation was relatively sparse as indicated by the high values for bare ground and litter (25%). A total of 102 species were observed in the dry-mesic sand prairie resulting in a FQI of 37.77 and a mean CC of 3.74.

Mesic Sand Prairie: One high-quality mesic to wet-mesic sand prairie occurred on the GRSWA (SW1/4 S17 T19N R9E; Fig. 2). This extensive area of approximately 34 ha in size had high species diversity and contained few exotic species. Topographic differences were responsible for the mosaic of sand species that existed here, varying from the dry-mesic sand prairies on the low dune ridges to sand

Table 1. Frequency (%), mean cover (% of total cover), and importance value (IV) of the ground layer species (with IVs >2.0) encountered in late summer of 2006 in a dry sand prairie, a dry-mesic sand prairie, and a mesic sand prairie, Green River State Wildlife Area, Lee County, Illinois. (n = 50) (*exotic species)

ponds in the small depressions. Mesic sand prairie vegetation occurred on the slopes of the dunes where the soils were comprised of Dakota sandy loam. In contrast, the wet-mesic prairie was on the lower ground between the dunes on Hoopeston fine sandy loam. *Sorghastrum nutans* and *Andropogon gerardii* were the dominant tall grasses, commonly being more than 1.6 m tall. Other common grasses included *Dichanthelium acuminatum*, *Agrostis gigantea*, and *Panicum virgatum* (Table 1). The important native forbs included *Parthenium integrifolium*, *Fragaria virginiana*, *Liatris pycnostachya*, *Desmodium illinoense*, and *Euthamia gymnospermoides* (Table 1). Based on the Sorensen Index of Similarity, the mesic sand prairie was similar to the dry mesic sand prairies, and has very low similarity to the wet sand prairie and sedge meadows (Table 2). A total of 44 taxa were encountered in the plots, including 3 exotic species. Bare ground and litter averaged 13%. A total of 124 species were observed in the mesic prairie resulting in a FQI of 45.21 and a mean CC of 4.06.

Wet Sand Prairie: A 5-ha wet sand prairie was located along the western and northern edges of a sedge meadow at the southeastern part of the GRSWA (NE1/4 SW1/4 S17 T19N R9E; Fig. 2). The vegetation of this prairie was transitional between the sedge meadow and wet-mesic to mesic sand prairie to the north and west. Here, changes in species composition occurred depending upon slight differences in elevation. *Spartina pectinatus* was the dominant grass, while *Carex haydenii* was the most important sedge. Common forbs included *Helianthus grosseserratus*, *Solidago canadensis*, *Onoclea sensibilis*, *Galium obtusum*, *Hypericum spha-*

erocarpum, and *Silphium integrifolium* all with IVs of 8.0 or higher (Table 3). Based on the Sorensen Index of Similarity, the wet sand prairie was similar to the mesic sand prairies and the sedge meadows, with low similarity to the drier sand communities (Table 2). Within the wet prairie 68 taxa were encountered, including three exotic species, *Poa pratensis* being the most important. Bare ground and litter averaged less than 2%. A total of 102 species were observed in the wet sand prairie for an FQI of 39.11 and a mean CC of 3.87.

Sedge Meadows: Hummocks were present throughout the sedge meadows, their height dependent on the distance from the sedge meadow center, i.e., smaller hummocks near the edge, larger and taller hummocks near the center. One small sedge meadow, covering less than 0.5 ha, occurred in a shallow depression near the southeast corner of GRSWA (NE1/4 SW1/4 S17 T19N R9E; Fig. 2) (sedge meadow East). *Bolboschoenus fluviatilis* was the most important species, followed by *Carex haydenii*. The common species recorded for this sedge meadow included *Thelypteris palustris*, *Onoclea sensibilis*, and *Aster praealtus*. At the south edge of this sedge meadow was a depression that likely represents an old sand pond that became partially filled and no longer holds water year around. *Bolboschoenus fluviatilis* dominated this depression, with *Persicaria amphibium* also common. A total of 44 species were observed in this sedge meadow, yielding a FQI of 30.30 and a mean CC of 4.57.

A 1.5-ha sedge meadow was located at the southeast corner of the marsh (SE1/4 NE1/4 S13 T19N R8E; Fig. 2) (sedge meadow West). In 2002 this sedge meadow was dominated by

Table 3. Frequency (%), mean cover (% of total cover), and importance value (IV) of the ground layer species (with IVs >2.0) encountered in late summer of 2006 in a wet sand prairie and an adjacent sedge meadow (sedge meadow East), Green River State Wildlife Area, Lee County, Illinois. (n = 50) (*exotic species)

Carex haydenii and *Calamagrostis canadensis*, with *Persicaria coccinea* also common (Table 4). Twenty-nine taxa including three exotic species were encountered in the plots: *Mentha arvensis* was extremely common, followed by *Chenopodium album* and *Persicaria vulgaris*. Though burned in 2005, no peat fires occurred here and the area was not subjected to disking. The three most important species in 2005 maintained their dominance during 2006 and 2007. Eleven additional species were found in the

plots in 2006. By 2007 most of these species were lost or greatly reduced in abundance, and the original dominants of 2002 had regained much of their previous importance. By 2007 two native forbs, *Teucrium canadense* and *Aster praealtus*, had become more obvious (Table 4). In 2002, a total of 42 species were observed in this sedge meadow for an FQI of 21.49 and a mean CC of 3.31.

Marsh: Located along the western edge of the GRSWA, the marsh was divided into five vegetation zones (W1/2 S13 T19N R8E; Fig. 2). Within this 40-ha marsh/sedge meadow complex the vegetation zones were mostly dependent on slight differences in elevation, soils, and past disturbance, particularly drainage attempts and fire frequency, intensity, and time of year. The transitions between the various vegetation zones were abrupt with the edges of the zones being very distinct. Of the 36 species encountered, including several conservative species, only 5 were exotics. The marsh FQI was 18.48 and the mean CC was 3.08. Much of this marsh area was burned in the fall of 2005.

***Phalaris* Vegetation Zone:** The exotic *Phalaris arundinacea* was the dominant species in shallow areas throughout the marsh where water level fluctuations were pronounced (Table 5). This disturbance community occurred in areas where water levels were usually low and flooding was of short duration. This zone was found throughout nearly all of the extensive wetlands at the GRSWA and accounted for nearly half of the marsh area. When surveyed in 2002, *Phalaris arundinacea* dominated, *Persicaria coccinea* was second, and six other species were encountered. In 2006, after the 2005 fire, *P. arundinacea* continued to dominate. Many other species were also present in 2006, but by 2007 many had disappeared (Table 5). Most notable was *Ambrosia artemisiifolia*, which in 2006 was second in importance, but was not found in the plots in 2007.

Salix interior thickets were common at the edge of the marsh as narrow bands at the base of the stabilized dunes. When surveyed in 2002, *Phalaris arundinacea* dominated the ground layer beneath these willow thickets; *Persicaria punctatum* was also common, whereas seven other species were occasionally encountered (Table 6). After the 2005 fire, *P. arundinacea* still dominated; *Urtica gracilis* was second in importance in 2006 but dropped to third by 2007. Five taxa not found in 2002 were encountered in 2006, and the number of new species had increased to 14 by 2007.

An extensive *Phalaris arundinacea* population occurred in a shallow depression near the middle of the GRSWA and close to the office building (SW1/4 NE1/4 S18 T19N R9E). During the 2005 fire, this entire area burned and extensive peat fires destroyed much of the peat; the depression was flooded and disked

in efforts to control the fires. *Phalaris arundinacea* was not recorded in any of the plots when the site was surveyed in 2006. Thirteen native species were present, although the exotic *Cirsium arvense* was the dominant taxon (Table 7). Other relatively important species included the native taxa *Oenothera biennis*, *Verbena hastata*, and *Persicaria punctata* along with the exotic *Chenopodium album*. By 2007 *P. arundinacea* had returned, *Cirsium arvense* had nearly disappeared and though many native weedy species had invaded, extensive areas of bare ground were present (Table 7).

***Typha/Persicaria* Vegetation Zone:** Scattered throughout the marsh in 2002 were extensive areas of *Typha latifolia* (Table 8). *Persicaria coccinea* and *Carex lacustris* were common among the cattails. Many other species were occasionally encountered, although none were very important, as indicated by low mean cover. *Typha latifolia* nearly disappeared following the fire, before increasing in importance in 2007 (Table 8). *Phalaris arundinacea* increased between 2005 and 2006, and by 2007 was the dominant species present. Fourteen additional species were recorded in these plots in 2006, whereas many had disappeared by 2007.

One extensive *Typha latifolia* population of 16 ha in size occurred next to the road at the western edge of the marsh, separated from the rest of the marsh by a narrow sand ridge. During the 2005 fire, much of this area burned and the fire destroyed extensive areas of peat, the fires smoldering for a few days. The depression was intentionally flooded and disked. Though the dominant species before the 2005 fire, *T. latifolia* was uncommon in 2006, but increased significantly in 2007 (Table 9). *Phalaris arundinacea*, which was rarely encountered before the 2005 fire, was the dominant species in 2006 and 2007.

***Bolboschoenus fluviatilis* Vegetation Zone:** *Bolboschoenus fluviatilis* was the dominant species in an area of about 1.2 ha (Table 10). *Persicaria coccinea*, *Sparganium eurycarpum*, and *Urtica gracilis* were common under the river bulrush. Only five species were found in the plots and no exotic species were encountered in 2002 (Table 10). After the 2005 fire, *B. fluviatilis* initially decreased and then increased in importance. Thirteen additional species were recorded in these plots in 2006, although many had disappeared by 2007. By 2007, *Persicaria coccinea* had recovered, *Sparganium eury-*

carpum was still recovering, whereas *Urtica gracilis* was not recorded.

***Sparganium eurycarpum* Vegetation Zone:** A few small areas of ≤ 0.5 ha were dominated by *Sparganium eurycarpum* (Table 11). *Persicaria coccinea* was also important followed by *Urtica gracilis*. Only eight species were found in the plots and the exotic *Phalaris arundinacea* was rarely encountered. After the 2005 fire, *S. eurycarpum* was absent from the plots and by 2007 was still uncommon. In contrast, *Persicaria coccinea* increased in important in 2006 and again in 2007. Thirteen additional species were recorded in these plots in 2006, whereas some were absent in 2007.

***Carex lacustris/Persicaria coccinea* Vegetation Zone:** Located next to the sedge meadow in the southeastern part of the marsh, this zone covered approximately 5 to 6 ha . The dominant species, *Carex lacustris*, *Persicaria coccinea*, and *Calamagrostis canadensis*, far exceed the importance of the other species present (Table 12). Thirteen species were encountered in the

plots with more than half having IVs of less than 1.5. Though burned in 2005, no peat fires occurred and the area was not subjected to disking. During the 2006 and 2007 surveys, the three dominant species maintained their importance. Seventeen additional species were found in the plots in 2006, including the native *Ambrosia artemisiifolia* and exotic *Chenopodium album*. By 2007 most of these species were absent or greatly reduced in abundance, and the original dominants of 2002 had regained much of their previous importance. By 2007 two native prairie forbs, *Teucrium canadense* and *Aster praealtus*, became much more abundant (Table 12).

Sand Pond: Scattered through the lowlands of the GRSWA were a few small sand ponds, none more than 55 m across. The vegetation surrounding these ponds varied extensively. Most ponds were located where *Phalaris arundinacea* dominated the pond margins with few other species being encountered. Around a few

Table 5. ponds, however, wet to wet-mesic sand prairie vegetation dominated depending on the steepness of the shoreline. No high-quality sand ponds were encountered during this study.

Sand Forest: Both lowland and upland forests were located at GRSWA (Fig. 2). The lowland forests were dominated by *Acer saccharinum* with a few subdominant species including *Prunus serotina*, *Populus deltoides*, *Juglans nigra*, *Acer negundo*, *Salix nigra*, and *Fraxinus pennsylvanica* (Sites 1, 2, 3, and 4, Table 13). In these forests *Acer saccharinum* was consistently of highest importance, highest density, and of relatively large size. In contrast, the upland forests were commonly dominated by *Prunus serotina* along with the exotic species *Morus alba* or *Robinia pseudoacacia* and some of the lowland forest species (Sites 5 and 6, Table 13). In both forest types the woody understory was dense, with many native and

exotic trees and shrubs common. Overall, woody seedling densities averaged between 6,000 and 16,000 stems/ha, small saplings averaged between 3,200 and 6,850 stems/ha, while large saplings were not common with an average between 0 and 740 stems/ha. The most abundant understory shrubs were mostly exotic species with *Elaeagnus umbellata*, *Lonicera maackii*, *Lonicera x bella*, *Rhamnus cathartica*, and *Rosa multiflora* common.

The ground layer in these six forest sites was similar. In addition to the numerous woody tree seedlings and shrub in the ground layer, many herbaceous species were common. Generally native herbs dominated, with *Ageratina altissima*, *Antenoron virginianum*, *Boehmeria cylindrica*, *Cryptotaenia canadensis*, *Geum canadense*, *Osmorhiza* sp., *Phytolacca americana*, *Solidago canadensis*, and *S. gigantea* being the most common taxa. A few exotic herbs such as *Alliaria petiolata*, *Bromus inermis*, *Fallopia convolvulus*,

Table 6. Frequency (%), mean cover (% of total cover), and importance value (IV) of the ground layer species encountered in late summer of 2002 and again in 2006 and 2007 in a *Phalaris arundinacea* vegetation zone community that is shaded under a thicket of *Salix interior* in the marsh at the western edge of the Green River State Wildlife Area, Lee County, Illinois. (n=50). (*exotic species)

and *Phalaris arundinacea* sometimes dominated.

Woody encroachment at the GRSWA had increased dramatically, based on the analysis of aerial photographs. In 1939, one year after the initial purchase of the land for the GRSWA, approximately 47.5 ha (4.6% cover) were covered by trees and large shrubs. The extent of the forested areas had increased to 72.2 ha (7% cover) by 1951, 184.9 ha (17.8% cover) in 1970, and 294.6 ha (29.4% cover) in 1988. Woody encroachment was most obvious along many of the original hedge rows and where pine plantations were introduced soon after the site was purchased.

In 2001 most of the forests at the GRSWA were clear-cut. Two of these resulting successional areas, a lowland and an upland site, were surveyed in 2002, 2003, and 2006. Of 47 taxa

recorded in 2002, *Phalaris arundinacea* and *Persicaria pensylvanica* dominated the lowland site (Table 14). In 2003, *P. arundinacea* continued to dominate with *Persicaria pensylvanica*, *Conyza canadensis*, *Potentilla norvegica*, and *Populus deltoids* seedlings important. *Phalaris arundinacea* dominated during the 2006 survey, whereas *Solidago canadensis*, *Persicaria pensylvanica*, *Lactuca serriola*, and *Chenopodium album* were among the most important of 58 species encountered (Table 14). Throughout the survey, *P. arundinacea* and *Persicaria pensylvanica* remained dominant members of the lowland community. Overall, 17 species were recorded in all 3 years of the study, with 23 taxa restricted to 2006, 20 found only in 2003, and 15 restricted to 2002; 28 exotic species were recorded in the lowland plots .

In 2002 *Phytolacca americana* dominated the upland site, with *Solanum ptychanthum*, *Chenopodium album*, *Lonicera maackii*, and *Cyperus schweinitzii* following in importance (Table 15). By 2003 *Conyza canadensis* dominated, followed by *Lonicera maackii*, *Verbascum thapsus*, and *Cyperus lupulinus*. In 2006 *Rubus pensilvanicus*, *Verbascum thapsus*, *Chenopodium album*, and *Lonicera maackii* were the important taxa. The number of taxa recorded in the plots varied from 41 to 48, including 21 exotic species.

DISCUSSION

Exotic Species: The sand prairie communities at the GRSWA had high species richness, many prairie conservative species, and few exotic taxa. Exotic species were usually present in low numbers, occurred in restricted areas, and were not major community components. Only three exotic species were consistently encountered in the plots of the upland sand prairies. These species, *Achillea millefolium*, *Rumex acetosella* and *Poa pratensis*, were mostly localized, and though sometimes recorded in high frequencies, they had low densities. In the wet sand prairie

the exotic species included *Poa pratensis*, *Lactuca serriola*, and *Rumex crispus*, all with very low numbers. In the sedge meadows four exotic species were recorded with *Mentha arvensis* being the most common. *Phalaris arundinacea* was the dominant species throughout most of the GRSWA lowlands, particularly the marsh. The abundance of *Phalaris arundinacea* at GRSWA is an indication of past disturbances, particularly the fluctuation of water levels due to attempts to drain these lowlands. Water table fluctuations resulting from large amounts of ground water being removed for irrigation has exacerbated the problem.

The exotic species *Morus alba* and *Robinia pseudoacacia* dominated the upland sand forests at GRSWA. These disturbed, poor-quality forests had become established due to the lack of fire. Associated shrubs on these wooded sites included the exotics *Elaeagnus umbellata*, *Lonicera maackii*, *L. x bella*, *Rhamnus cathartica*, and *Rosa multiflora*, which in many areas created impenetrable thickets. When these forested areas were clear-cut in 2001, no slash was

left on the ground, and the woody understory was removed. All that was left were stumps that were cut very close to the ground, along with mostly bare sand and some areas covered with a layer of litter. A majority of the species colonizing these areas were exotic and native weedy species.

Endangered Species: Few endangered and threatened species were encountered in GRSWA, probably the result of poor management prior to 1993. *Botrychium matricariifolium* was the only endangered species found at the GRSWA, occurring at the edge of a mesic sand prairie beneath individuals of *Lonicera maackii*. Three threatened species were found: *Lechea intermedia*, *Orobanche ludoviciana*, and *Platanthera flava* var. *helbiola* (Herkert and Ebinger 2002, Illinois Endangered Species Protection Board 2005).

Dry Sand Prairie: The dry sand prairie at GRSWA was similar to the one located at Foley Nature Preserve (FNP; McFall and Karnes

1995, McClain et al. 2003). Located in the extreme western part of Lee County (SW1/4 S7 T20N R8E), this preserve covers the entire ridge and slopes of a small dune, and contains a 2.8-ha dry to dry-mesic sand prairie remnant. *Schizachyrium scoparium* dominated both areas and many forbs were common to both sites. Common forbs at FNP were *Euphorbia corollata*, *Aster ericoides*, *Echinacea pallida*, *Coreopsis palmata*, and *Ambrosia psilostachya*, while *Amorpha canescens* was the common shrub. Species diversity at FNP was higher than at the GRSWA, however, and more conservative prairie species were present as indicated by an FQI of 52.98 and a mean CC of 3.96 (McClain et al. 2003) compared to an FQI of 36.16 and a mean CC of 3.73 at GRSWA. This may be the result of an older, more aggressive management program at the former, although disturbance prior to public acquisition was probably more

important. The low numbers of exotic taxa, along with presence of native and conservative prairie taxa, indicate that both sites were recovering from past disturbances.

The dry sand prairie at GRSWA is also similar to a small prairie remnant at the Richardson Wildlife Foundation (RWF). Located about 13 km east of Amboy, Lee County, Illinois (S13, S14, S3, S24, T20N R11E), the RWF is located near the southwestern edge of what was the Great Inlet Swamp (Killey 1998, Handel et

al. 2003). This swamp covered approximately 12,000 ha, and existed because of the Dewey Dam, a natural limestone obstruction 8 km northeast of the town of Amboy, which prevented channel formation by the Green River (Lyman 1901). In the late 1880s, work began to drain this extensive swamp. Efforts to save the swamp and keep it as a wildlife sanctuary failed, and by 1901 the swamp was gone (McClain 1992, McClain and Ebinger 2000). After drainage most of the Great Inlet Swamp

was farmed, but many smaller tracts were left for cattle grazing. As of 1999, 15 ha of sand prairie and sedge meadow remnants existed on the RWF.

This dry sand prairie remnant at RWF was more mesic than the dry sand prairie at GR-SWA since the dunes in this part of the Green River Lowlands are smaller and the water table is closer to the surface. On this dry sand prairie *Sorghastrum nutans* dominated, followed by *Euthamia graminifolia* *Schizachyrium scoparium*, *Solidago nemoralis*, *Liatris aspera*, and *Viola sagittata*. Diversity was low, with only 46 species, including the exotic *Rumex acetosella*, *Poa pratensis*, and *Achillea millefolium*, recorded (Handel et al. 2003). The FQI of this

dry sand prairie was 29.28 and the mean CC was 4.18.

Dry-mesic Sand Prairie: *Sorghastrum nutans* was the dominant native grass in the dry-mesic sand prairies at both GRSWA and RWF (Handel et al. 2003). *Andropogon gerardii*, in contrast, was important at GRSWA, but nearly absent at RWF. *Dichanthelium villosissimum*, a low-growing bunch grass, was fifth in importance at GRSWA but was not encountered at RWF. The dominant forbs on the RWF were *Solidago nemoralis*, *Parthenium integrifolium*, and *Euthamia graminifolia*. Only about half of the species were common to both sites; however, RWF was relatively rich in conservative

Table 15. species that were not found at GRSWA. The FQI was 41.88 and the mean CC was 4.44 at RWF (compared to FQI of 37.77, mean CC of 3.74 at GRSWA).

Mesic Sand Prairie: The mesic to wet-mesic sand prairies at RWF and GRSWA differed in species composition (Handel et al. 2003). On both sites *Sorghastrum nutans* and *Andropogon gerardii* were the dominant tall grasses. Also, at both sites forb diversity was high, but few of the species encountered at the GRSWA were found at RWF, and except for the dominant tall grasses there was almost no similarity between the two sites. The mesic sand prairie at RWF had a higher FQI and mean CC than at GRSWA. Overall, there were fewer native prairie species at GRSWA and most were not conservative species. Past destructive management practices (including food plot plantings, lack of fire, and equestrian use) at GRSWA prior to 1993 were probably responsible for these differences.

Wet Sand Prairie: The only wet sand prairie examined in the Green River Lowlands was associated with a sedge meadow/mesic prairie area at GRSWA. This plant community is similar in species composition to wet "black soil" prairies with *Spartina pectinatus*, *Calamagrostis canadensis*, *Thelypteris palustris* and various *Carex* species common (White and Madany 1978). The wet sand prairie at GRSWA, with 102 taxa, had the highest species diversity of all communities encountered. Many were rare species with very specific habitat requirements, some of which were common throughout the wet prairie.

Sedge Meadow: Sedge meadows are relatively common in the preserves of the Green River Lowlands. Two were studied at GRSWA, whereas three at RWF had earlier been examined (Handel et al. 2003). All were similar in having extensive hummocks of *Carex haydenii*, the dominant species. The species commonly encountered at RWF included *Onoclea sensibilis*, *Thelypteris palustris*, *Calamagrostis canadensis*, *Helianthus grosseserratus*, *Boehmeria cylindrica*, *Solidago gigantea*, and *Galium obtusum*; many of the same species encountered at the GRSWA sedge meadows. The sedge meadows at RWF averaged between 39 and 54 species, compared to 25 to 29

species at GRSWA. The reason for the lower species diversity at the GRSWA is not known, but is undoubtedly related to the nature of past disturbances, and more active management, especially water table manipulation, at RWF.

Marsh: The only marsh examined in the Green River Lowlands, located at the western edge of the GRSWA, was surveyed in 2002, subjected to an uncontrolled burn in 2005, and surveyed again in late summer of 2006 and 2007. During 2002 species diversity was very low, composed mainly of species found in many marsh communities throughout most of Illinois (White and Madany 1978). The first year after the 2005 fire, many native weedy species became important, whereas the original dominant species were either absent or present in low numbers. By 2007 many of these native weedy species were greatly reduced in numbers or were absent altogether, whereas many of the species dominant in 2002 were recovering. One exception was *Sparganium eurycarpum*, which had not recovered by 2007. It appears that this species does not do well after hot fires, many of the rhizomes likely did not survive. Many of the less abundant species that were present in 2002 were not observed in the later surveys as they were never important stand components.

Sand Forest: Based on General Land Office (GLO) survey notes and plats, the pre-settlement sand deposits of the Green River Lowlands were dominated by sand prairies and marshes. The dominant tree on sand dunes was *Quercus velutina*, mostly occurring as scattered individuals on dune ridges and protected sites. These savannas consisted of open-growth trees and ground cover dominated by sand prairie grasses and forbs (Curtis 1959, Bray 1960, Nuzzo 1986, White and Madany 1978). In dry sand savannas the soil lacked a dark A horizon and the ground cover was composed of many prairie species with the dominant bunchgrasses, which were typically less than 1 m tall. These dry sand savannas and forests were associated with dune and swale topography, which probably limited the severity of fires. Common lowland species of the Green River Lowlands were probably *Acer saccharinum*, *Celtis occidentalis*, *Fraxinus pennsylvanica*, *Populus deltoides*, *Prunus serotina*, and *Salix nigra*. Frequent prairie fires prevented these fast growing tree species from covering large areas

of the wetland and lower dune slopes (McClain and Elzinga 1994). These fast-growing, fire-sensitive, shade-intolerant taxa were all common forest components at GRSWA during this study.

The forests present at GRSWA during this study were of recent origin. Post-settlement fire suppression had increased the acreage of sand forest at the expense of sand savannas (White and Madany 1978, Anderson and Brown 1986, Anderson 1991, Abrams 1992). These forests, with 80 to 100% canopy cover, had eliminated the common prairie and marsh plants associated with the dune and swale topography typical of Illinois sand deposits.

Management: The management of prairie and marsh communities at GRSWA since 1993, which has included the use of fire on a regular basis and the active removal of brush and trees, has been important in improving the quality of these communities. The high importance values of some exotic species, particularly *Phalaris arundinacea*, indicated that some areas were not recovering rapidly from past disturbances. The presence of the native and conservative prairie taxa, however, indicated that the management practices had, in part, been successful. The use of fire is imperative if the upland sand prairie communities are going to increase in quality and species diversity (Bowles et al. 2003).

ACKNOWLEDGMENTS

The authors thank the Illinois Department of Natural Resources for funding parts of this project through the Illinois Wildlife Preservation Fund as well as other funding sources, the Illinois Nature Preserves Commission for allowing access to the nature preserves, Dr. Gordon Tucker, Eastern Illinois University, for his help in identification of the Cyperaceae, and Ms. Katherine J. Hunter, Illinois Natural History Survey, for digitizing the data on woody encroachment. P. Sorensen and an anonymous reviewer provided constructive comments on the manuscript.

APPENDIX I

Vascular plant species encountered at Green River State Wildlife Area, Lee County, Illinois, are listed alphabetically by family under major plant groups. Collecting numbers preceded by an E (John E. Ebinger) are deposited in the Stover-Ebinger Herbarium, Eastern Illinois University, Charleston, Illinois (EIU). Collecting numbers preceded by a P (Loy R. Phillippe) are deposited in the Illinois Natural History Survey Herbarium, Champaign. (ILLS). (*exotic species)

FERNS AND FERN-ALLIES

Aspleniaceae

Asplenium platyneuron (L.) Oakes: P32588

Dryopteridaceae

Athyrium filix-femina (L.) Martens ssp. *angustum* (Willd.) R.T. Clausen: P32587

Dryopteris carthusiana (Villars) H.P. Fuchs: P32576

Dryopteris cristata (L.) Gray: P31662

Equisetaceae

Equisetum arvense L.: P31501

Equisetum x *ferrissii* Clute: P31638

Equisetum hyemale L.: P32602

Equisetum laevigatum A. Br.: P31644

Onocleaceae

Onoclea sensibilis L.: P32370

Ophioglossaceae

Botrychium dissectum Spreng.: P32530

Botrychium matricariifolium (Doll.) A. Br.: P31628

Botrychium virginianum (L.) Sw.: P31608

Osmundaceae

Osmunda claytoniana L.: P31483

Osmunda regalis L.: P31577

Thelypteridaceae

Thelypteris palustris Schott: P32451

GYMNOSPERMS
